

The one timing asymmetry in the design, measured instead of conceded

Credit-batching left quote age bimodal, which makes it a natural experiment: the split is the collector's cadence, not a property of the games. Every interval on the right covers zero.

A batched collector split the sample for us

and the staleness penalty is real but tiny

book_freshness.log \$1-\$2 · a POSITIVE shift means the exchange's apparent edge shrinks once the book is quoted fresh — the handicap the caveat feared. All four are insignificant ($z = 0.14-1.30$).
